Reversyl (Resveratrol) — The Research So Far

Resveratrol is a polyphenol compound found naturally in the skin of red grapes, certain berries, and peanuts. It has been studied extensively in cell and animal research, and increasingly in human clinical trials, because of the way it interacts with several pathways involved in metabolism, inflammation, and cell aging.

How Resveratrol Is Thought to Work

Laboratory research has focused on a handful of biological pathways that resveratrol appears to interact with:

- SIRT1 — a protein linked to cellular stress responses and energy metabolism
- AMPK — often called the cell's "energy sensor"
- Nrf2 — a master switch for the body's own antioxidant enzymes
- NF-κB — a signaling pathway involved in inflammation

These pathways help explain why researchers keep studying resveratrol. They are mechanistic findings, not proof of a specific outcome in people — a change observed in a cell or animal study does not automatically mean a person taking a resveratrol supplement will experience the same effect.

What Human Research Has Looked At

Clinical studies and reviews of resveratrol supplementation in humans have investigated outcomes including:

- Blood pressure and blood vessel (endothelial) function, particularly in people with type 2 diabetes
- Waist circumference and other measures of central body fat
- Cholesterol and other blood lipid levels, especially in people who are overweight
- Blood sugar control, insulin resistance, and markers such as HbA1c
- Inflammation markers such as CRP
- Memory and cognitive test performance

Several reviews of these trials describe the improvements in these areas as modest, and note that results differ from study to study depending on the dose, the formulation used, the length of the study, and who was studied. A recurring theme across independent reviews is that resveratrol is poorly absorbed in its active form, which may help explain why human results are smaller and more inconsistent than the laboratory findings on its own would suggest.

What the Research Does Not Show

- That resveratrol extends human lifespan or reverses aging
- That resveratrol prevents or treats cancer
- That resveratrol prevents or reverses diabetes
- That resveratrol prevents cardiovascular disease in otherwise healthy people
- That resveratrol replaces medical treatment for any condition

Safety Notes

Resveratrol has generally been well tolerated in the doses used in published human trials. As with any supplement, it should be avoided during pregnancy and breastfeeding, and anyone with a medical condition or taking medication should speak with their doctor before starting it.
